This book explores the life and scientific legacy of Manfred Schroeder through personal reflections, scientific essays and Schroeder's own memoirs. Reflecting the wide range of Schroeder's activities, the first part of the book contains thirteen articles written by his colleagues and former students. Topics discussed include his early, pioneering contributions to the understanding of statistical room acoustics and to the measurement of reverberation time; his introduction of digital signal processing methods into acoustics; his use of ray tracing methods to study sound decay in rooms and his achievements in echo and feedback suppression and in noise reduction. Other chapters cover his seminal research in speech processing including the use of predictive coding to reduce audio bandwidth which led to various code-excited linear prediction schemes, today used extensively for speech coding. Several chapters discuss Schroeder's work in low-peak factor signals, number theory, and maximum-length sequences with key applications in hearing research, diffraction gratings, artificial reverberators and de-correlation techniques for enhancing subjective envelopment in surround sound. In style, the articles range from truly scientific to conversationally personal. In all contributions, the relationship between the current research presented and Manfred Schroeder's own fields of interest is, in general, evident. The second part of the book consists of Schroeder's own memoirs, written over the final decade of his life. These recollections shed light on many aspects not only of Schroeder's life but also on that of many of his colleagues, friends and contemporaries. They portray political, social and scientific events over a period that extends from pre-war to the present. These memoirs, written in an inimitable and witty style, are full of information, entertaining and fun to read, providing key insight into the life and work of one of the greatest acousticians of the 20th century.

To derive an optimum design of a MEMS microphone in any application (i.e. photoacoustic instrumentation), it is important to understand the underlying physics that govern the behavior of the device. In addition, one must have a good understanding of the specific requirements imposed on the device in the intended application. In the particular case of photoacoustic detection, signal-to-noise ratio is the overwhelmingly important parameter. Other parameters such as size and required operating voltage may be compromised to achieve the best possible signal-to-noise ratio. An important property, to be shown below, is the low sensitivity to vibration in MEMS microphones due to a much smaller mass of inertia of the sensing diaphragm, when compared to state-of-the-art conventional microphones. In photoacoustic detection, a microphone is used to detect the minute thermal expansion/pressure wave generated in a gas due to molecular absorption, and subsequent release, of energy generated from a light source 1.6. This method is very well suited for molecular fingerprinting, since the absorption versus applied light energy/wavelength is uniquely dependent on the exact molecular structure. The measurement, in which light of various wavelengths is applied, to map the molecular absorption, is referred to as photoacoustic spectroscopy (PAS). Current PAS instrumentation utilizes state-of-the-art conventional microphone technology in combination with high powered light sources to maximize the sensitivity of the system. It is well known from literature (such as 2), that electrostatic, or capacitive, microphones have the highest sensitivity and the lowest self-noise of the known detection principles. While conventional capacitive microphones provide excellent signal-to-noise ratio, there is a significant problem with vibration-borne artifacts.

This thesis work determines the far-field array response patterns of micro-electromechanical system (MEMS) microphone arrays; and verifies these patterns employing experimental methods. Phase shifts and amplitude behaviour are simulated through finite element methods (FEM) using COMSOL Multiphysics, under both ideal and realistic conditions. Physical measurements are performed with microphone arrays using high accuracy audio analyzer equipment (Audio Precision APX555) to support and compare with mathematical and simulation conclusions. The effects of the packaging, mounting materials, and interference among elements on the array response patterns are studied using two-element microphone arrays. A new form of MEMS microphone array beamformer - a dynamic layout array beamformer - is introduced and simulated with the goals of improving flexibility, while lowering the complexity and power consumption, of MEMS microphone array systems. In addition to the acoustic signal recognition, a new approach is developed with a Xilinx Basys3 FPGA board to record and analyze the audio files using PmodMIC3 MEMS microphone devices. Applications based on the MEMS microphone array beamforming are introduced. Potential applications of the research to intelligent transportation system (ITS) moving vehicle direction of arrival (DOA) estimation are presented for further study.
